CHAPTER 1

Introduction

Virtuozzo 6 is a virtualization solution that allows you to run multiple virtual machines and Containers on a single physical server.

This chapter provides general information about Virtuozzo and this guide.

- Virtuozzo basics (p. 5)
- goals and target audience of the guide (p. 6)
- guide organization (p. 6)
- resources to consult to get more information on Virtuozzo (p. 7)
- ways to submit feedback to the documentation team

In This Chapter

About Virtuozzo 6	5
About This Guide	6
Getting Help	7

About Virtuozzo 6

Virtuozzo 6 is a virtualization solution that allows you to simultaneously run multiple virtual machines and Containers on a single physical server. With Virtuozzo, you can efficiently share your server's hardware resources among virtual machines and Containers.

Virtuozzo is installed directly on the server hardware and does not need any operating system to function. Once it is installed, Virtuozzo allows you to create virtual machines and Containers and manage them using the following tools:

- **Command-line interface (CLI)**. The command-line interface comprises a set of command-line utilities that you can use to manage virtual machines and Containers, both locally and remotely.
- Virtuozzo Automator. Virtuozzo Automator is a remote management tool that allows you to manage physical servers and their virtual machines and Containers with the help of a standard Web browser on any platform.

Graphically, a server with the Virtuozzo software installed can be represented as follows:

About This Guide

This guide is meant to provide complete information on templates, a Virtuozzo technology allowing you to efficiently deploy standard Linux applications inside your Containers and to greatly save your host resources (physical memory, disk space, etc.). In particular, you will learn how to create your own application templates and manage them in a number of different ways.

The primary audience for this guide is anyone who is intended to deploy one or several applications inside their Containers and looking for ways to do it with the maximal level of efficiency. To complete all the operations described in this guide, no more than basic Linux administration habits is required.

Organization of This Guide

This guide is organized in the following way:

Chapter 1, Introduction (p. 5), gives an overview of the Virtuozzo product and this guide.

Chapter 2, Templates Overview (p. 8), provides general information on Virtuozzo templates: what templates are, the advantages of their usage in Virtuozzo-based systems, etc.

Chapter 3, Managing EZ Templates (p. 15), provides instructions on managing OS and application EZ templates. You will know how to create and install EZ templates on the host, add them to and remove them from Containers, make OS template caches and update them, etc.

Getting Help

In addition to this guide, there are a number of other resources available for Virtuozzo which can help you use the product more effectively. These resources include:

- *Virtuozzo 6 Installation Guide*. This guide provides detailed information on installing Virtuozzo on your server, including the pre-requisites and the stages you shall pass.
- *Installing via PXE*. This guide provides information on installing Virtuozzo 6 over a network using a PXE (Preboot Execution Environment) server.
- Getting Started With Virtuozzo 6. This guide provides basic information on how to install Virtuozzo on your server, create new Containers and virtual machines, and perform main operations on them. Unlike the Virtuozzo 6 Installation Guide, it does not contain detailed description of all the operations needed to install and set Virtuozzo to work (for example, installing Virtuozzo in unattended mode).
- *Virtuozzo 6 User's Guide*. This guide provides comprehensive information on Virtuozzo covering the necessary theoretical conceptions as well as all practical aspects of working with the product. However, it does not deal with the process of installing and configuring your system.
- *Virtuozzo Storage Administrator's Guide*. This guide is intended for system administrators interested in deploying Virtuozzo Storage in their networks.
- *Virtuozzo 6 Command Line Reference Guide*. This guide is a complete reference on all Virtuozzo configuration files and command-line utilities.

CHAPTER 2

Templates Overview

A template in Virtuozzo 6 is a set of application and configuration files installed on a host in such a way as to be usable by any Container. Virtuozzo provides tools for creating templates, installing and removing them on/from hosts, adding them to Containers, and so on.

Using templates, you can:

- Securely share RAM among similar applications running in different Containers to save hundreds of megabytes of memory
- Install applications and patches simultaneously in many Containers
- Use different versions of an application on different Containers (for example, perform an upgrade only in certain Containers)

There are two types of templates in Virtuozzo. These are OS templates and application templates. An OS template is an operating system and the standard set of applications to be found right after the installation. Virtuozzo uses OS templates to create new Containers with a pre-installed operating system. An application template is a set of repackaged software packages optionally accompanied with configuration scripts. Virtuozzo uses application templates to add extra software to existing Containers. For example, you can create a Container on the basis of the redhat OS template and add the MySQL application to it with the help of the mysql template.

In Virtuozzo, you can perform the following operations on templates:

- create new application templates
- list the templates currently installed on the host
- install templates on and remove them from the host
- add templates to Containers
- remove templates from the host and from Containers
- migrate templates from one host to another

All these operations are described in Managing EZ Templates (p. 15) in detail.

Note: The current version of Virtuozzo does not support using templates in virtual machines.

In This Chapter

EZ Templates Basics	9
EZ Template Directory Structure	10
Differences Between OS and Application EZ Templates	13
EZ Template Life Cycle	13

EZ Templates Basics

All OS and application EZ templates are defined by the following features:

• EZ templates do not carry the necessary package files inside themselves. They contain only the information about what packages should be installed on the host to make the templates fully operational and from what network repository these packages should be downloaded.

Note: For the sake of brevity, we will be saying throughout this guide that packages are included in EZ templates, which actually means that EZ templates contain the information on the corresponding packages without carrying the packages themselves.

- The dependencies of software packages included in an EZ template are automatically resolved during the packages installation on the host. So, if the specified packages require other packages to be installed, these packages are also downloaded from the repository and installed on the server. In case a package has requirements that conflict with existing software on the server or any dependencies for the package being installed cannot be satisfied, the package installation process fails without making any changes to the system.
- The EZ templates technology allows you to use the original OS and application vendor's packages and to receive the updated packages from a central repository right after their release.

One of the basic concepts in the EZ template technology is the concept of 'repository' where software packages for the given EZ template are stored. A repository is a prepared directory or website containing the packages and index files for Linux operating systems and/or any of their applications. An example of such a repository is the repository located at the http://mirrors.usc.edu/pub/linux/distributions/fedora/ website and storing software packages for Fedora Core releases. Using repositories gives you the following advantages:

- Software packages included in the given EZ template do not contain versions, but only names (e.g. bash, crontabs). So, you always update any package included in the EZ template to its latest version available in the repository.
- As a result of the fact that a list of packages does not provide their versions, EZ templates do
 not have versions either (e.g. redhat-el5-x86). Thus, you install any EZ template on the host
 only once and, after that, use the installed template to update the packages inside any
 Container where it is applied.
- You can create several OS EZ template sets for one and the same Linux operating system. Any OS EZ template you are provided with has the default packages set included in it and is called

the base OS EZ template. However, you can make your own OS EZ template sets (the socalled non-base OS EZ template sets) which may differ from the corresponding base template:

- in the number of packages included in these EZ template sets
- in the number and location of repositories to be used for these EZ template sets
- in the number and kind of scripts to be executed on different EZ template sets life cycle stages

Non-base OS EZ template sets must have their own names and are created by appending a random identifier to the base OS EZ template name. For example, if you wish your Container to run Red Hat Enterprise Linux 5 and to function as a Linux-based server only, you can create the redhat-e15-x86-server OS EZ template set and include only those packages in it that are needed for performing main server tasks. So, you can specify packages to be used for setting up file and print sharing and exclude all the packages for graphical interfaces (GNOME and KDE).

Virtuozzo provides you with a vzpkg tool allowing you to automatically locate and obtain the correct packages for your EZ templates from one or several package repositories. The packages are downloaded from the repository and installed on the host in one of the following cases:

- when creating a cache for an OS EZ template
- when updating an existing OS EZ template cache (if there are new packages available in the repository)
- when adding an application EZ template or package to the first Container
- when updating EZ templates or software packages inside a destination Container

Note: For details on how to manage software package repositories, see **Setting Up Repository and Proxy Servers for EZ Templates** (p. 21).

EZ Template Directory Structure

All EZ templates and the software packages included in them and installed on the host are located in the so-called template area the path to which is set as the value of the TEMPLATE variable in the /etc/vz/vz.conf file. By default, the /vz/template directory is used. The template area includes two main subdirectories:

- The cache subdirectory where the tar archive of the potential private area of a Container based on the corresponding OS EZ template is stored. The tar archive is created during the OS EZ template caching. Keep in mind that the OS EZ template should be obligatorily cached before you can start creating Containers on its basis.
- The template directory having the name of <os_name>/<os_version>/<arch> where:
 - <os_name> denotes the name of the Linux distribution for which the OS EZ template is created (e.g. redhat, centos).

- <os_version> is the version of the Linux distribution specified as <os_name> (e.g., 5 or 6).
- <arch> denotes the microprocessor architecture where the OS EZ template is to be run (x86, x86-64, ia64).

For example, after installing the 32-bit version of the Centos 6 EZ template, the /vz/template/centos/6/x86 directory on the host is created.

In its turn, the *arch* directory contains the following subdirectories and areas:

- The template configuration subdirectory including:
 - The config/os/default directory where the appropriate configuration files for the base OS EZ template are stored.
 - The config/os/<setname> directory where the appropriate configuration files for nonbase OS EZ templates, if any, are stored.
 - The config/app/<app_name>/default directory where the appropriate configuration files for the base application EZ template are stored. This directory is created if at least one application EZ template for the given OS EZ template is installed on the host.
 - The config/app/<app_name>/<setname> directory where the appropriate configuration files for non-base application EZ templates, if any, are stored.
- The packages area containing a number of software packages downloaded from the repository and installed on the host. An installed package has the following structure:

<name>-<epoch>:<version>-<release>.<arch>

where:

- <*name*> is the package name.
- <*epoch*> denotes the package epoch.
- <version> indicates the package version.
- <*release*> is the package release.
- *<arch>* denotes the microprocessor architecture where the package is to be used.
- One or several subdirectories containing the packages comprising the corresponding OS EZ template. The directories have the following names:
 - baseN for the base OS template
 - <setname>N for the non-base OS template with the name of <setname>, if any
 - <appname>N for the base application template
 - <appname>-<setname>N for the application template with the name of <setname>, if any

N denotes the index number of the URL specified in the repositories/mirrorlist file (see the information on the repositories/mirrorlist file below).

As has been mentioned above, the configuration directory (i.e.

/<template_area>/<template_directory>/config) contains a number of subdirectories
storing 'EZ templates'-related configuration files. The contents of these subdirectories can vary
depending on whether it is a base OS EZ template or a non-base one and on the EZ template type
(OS or application template). The most important configuration files are listed below:

- Data files:
 - packages: contains a list of software packages names included in the corresponding EZ template.
 - package_manager: specifies the packaging system used to handle the EZ template.
 - repositories: a list of repositories where the packages comprising the EZ template are stored.
 - mirrorlist: one or several URLs to the file containing a list of repositories from where the packages comprising the EZ template are to be downloaded.
 - distribution: the name of the Linux distribution for which the EZ template is created. This file should be absent for application EZ templates.
 - summary: brief information on the EZ template.
 - description: detailed information on the EZ template. As distinct from the summary file, it can contain additional data relevant for the EZ template.
 - environment: a list of environment variables set in the form of *key=value*.
- Scripts:
 - pre-cache: this script is executed before installing the packages included in the EZ template on the host.
 - post-cache: this script is executed after installing the packages included in the EZ template on the host.
 - pre-install: this script is executed before adding the EZ template to or installing the package inside the Container.
 - post-install: this script is executed after adding the EZ template to or installing the package inside the Container.
 - pre-upgrade: this script is executed before updating the packages inside the Container.
 - post-upgrade: this script is executed updating the packages inside the Container.
 - pre-remove: this script is executed before removing the application EZ template/package from the Container.
 - post-remove: this script is executed after removing the application EZ template/package from the Container.
- Document files: one or several files with arbitrary names containing the information on the EZ template (e.g. README).

Note: Detailed information on the files contained in the OS template configuration directory is provided in the *Virtuozzo 6 Command Line Reference Guide*.

While working with EZ template configuration files, keep in mind the following:

- The packages file should be specified for all EZ templates.
- The packages, package_manager, and repositories/mirrorlist files should be specified for all base OS EZ templates.
- The package_manager and distribution files should be specified for all base OS EZ templates and absent for non-base OS EZ templates and all application EZ templates.

The information from the repositories/mirrorlist files created for non-base OS and all application EZ templates is added to that in the repositories/mirrorlist files for the base OS EZ template.

Differences Between OS and Application EZ Templates

Listed below are the major differences between OS and application EZ templates:

- OS templates are used to create new Containers, whereas application templates provide additional software for already created Containers.
- OS templates may and usually do use action scripts, whereas application templates cannot use action scripts in the current version of Virtuozzo.
- You may define a list of compatible templates and a list of required templates for application templates.

EZ Template Life Cycle

An EZ template has the following development stages:

- 1 Any EZ template should be first installed on the host. The vzpkg install template command enables you to install OS and application EZ templates on the server.
- 2 The EZ template should be cached by using the vzpkg create cache command. This step is required for OS EZ templates only. As a result of the vzpkg create cache execution, the necessary packages included in the OS EZ template are downloaded from the network repository, installed in the /vz/template/<os_name>/<os_version> directory on the host, and a gzipped tarball for the OS EZ template is created and put to the /vz/template/cache directory.
- 3 Either a new Container is created on the basis of the cached OS EZ template with the prlctl create command or an application EZ template is added to any number of Containers by

using the vzpkg install command. In the latter case, the necessary application files are downloaded from the network repository, installed on the host, and then added to the Container private area.

- 4 An obsolete EZ template applied to the corresponding Container can be updated by using the vzpkg update command.
- **5** Any EZ template excluding OS EZ templates can be removed from the Container with the vzpkg remove command.
- 6 An EZ template that is not used by any Container may be completely removed from the host with the vzpkg remove template command.

CHAPTER 3

Managing EZ Templates

The given chapter describes the main operations you are likely to perform on Virtuozzo EZ templates.

In This Chapter

Creating an EZ Template	15
Setting Up Repositories and Proxy Servers for EZ Templates	21
Preparing an OS EZ Template for Container Creation	30
Installing Application EZ Templates on the Server	32
Viewing Installed EZ Templates on the Server	32
Viewing Available EZ Templates on the Server	33
Keeping EZ Templates Up To Date	33
Adding Application EZ Templates to Containers	35
Copying EZ Templates to Another Server	36
Removing an Application from Containers	37
Removing EZ Templates From the Server	37

Creating an EZ Template

Virtuozzo is shipped with a certain number of OS (e.g., $centos-6-x86_64$) and application (e.g., $mysql-centos-6-x86_64$) EZ templates. This is usually sufficient to deploy the main Linux distributions and their applications in Containers. You can, however, create your own OS and application EZ templates and use them to base Containers on or run different applications in Containers.

You can use one of the following ways to create EZ templates:

- Make a template on the basis of an existing template (p. 16). In this case, you configure the parameters of one of the templates installed on your server to meet your needs.
- Make a template from scratch (p. 16). In this case, you first create a new template configuration and then create the template on its basis.

The following subsections describe both ways of creating templates in detail.

Creating a Template from Official Templates

The easiest way to create a template is to base it on one of the official templates shipped by Virtuozzo and adjust its configuration to meet your demands:

- 1 Install the template you want to use as the basis for your new template (e.g., using the yum install command).
- 2 Create a copy of the directory containing the template configuration files. Depending on whether you want to create a non-base template or a self-contained template, your steps slightly differ:
 - To create a non-base template, create a subdirectory in the /vz/template/os_name/os_version/arch/config/os directory and copy to this directory the contents of the

```
/vz/template/os_name/os_version/arch/config/os/default subdirectory.
For example, to make a non-base template for the official centos-6-x86_64 template
and put its configuration files to the /customized directory, you can run this command:
```

cp -a /vz/template/centos/6/x86_64/config/os/{default,customized}

Note: Non-base OS EZ templates inherit some properties from their base OS EZ templates. So, before installing a non-base OS EZ template, make sure that the corresponding base OS EZ template is installed on the server.

• To create a self-contained template, create a subdirectory in the

/vz/template/os_name directory and copy to this directory the contents of the subdirectory for the original template (/vz/template/os_name/os_version). For example, to make a self-contained template on the basis of the official centos-6-x86_64 template and put it to the /vz/template/centos/6-customized directory, you can run these commands:

mkdir -p /vz/template/centos-customized/6/x86_64/config
cp -a /vz/template/centos{,-customized}/6/x86_64/config/os

3 Change to the directory containing the configuration files for the new template and adjust them to meet your demands. For example, you can change the list of packages to include in the template by editing the packages file or configure the list of mirrors by editing the mirrorlist file.

Creating a Template from Scratch

The process of creating a template from scratch includes completing the following tasks:

- 1 Installing the vztt-build package on the server.
- 2 Making a metafile that will be used as the basis for creating the template.
- **3** Using the vzmktmpl utility to create the template from the metafile.

The following subsections describe these operations in detail.

Installing vztt-build

The first step in creating a template from scratch is to install the vztt-build package on your server. This package contains

- template metafile samples. You use metafile samples as the basis for creating a metafile for your own template.
- the vzmktmpl utility. You use the vzmktmpl utility to create the template on the basis of your metafile.

The vztt-build package is available in the remote official repository so you can install it using the following command:

yum install vztt-build

Creating Metafiles

In the second step, you make a metafile, a plain text file having the .metafile extension and containing a list of parameters for your template. The vzmktmpl utility uses this file when creating the template.

The following example demonstrates the process of creating a metafile for the CentOS 6 x64 OS template. To create the metafile:

1 Create a new text file with an arbitrary name and the.metafile extension (e.g., centos-6-custom.metafile).

The easiest way to create a new metafile is to copy one of the metafile samples from the /usr/share/vztt/samples directory and configure it to meet your demands. For example, you can use the /usr/share/vztt/samples/centos-6-x86_64/metafile file as the basis for creating your new metafile for CentOS 6.

cp /usr/share/vztt/samples/centos-6-x86_64/metafile /home/user1

- 2 Configure the metafile to meet your demands:
 - **a** %osname. Specify the name of the Linux distribution for which you are creating the OS EZ template:

```
%osname
centos-custom
```

The specified name will be assigned to the template directory where you will install the template (e.g., in our case, it will be /vz/template/centos-custom).

b %osver. Specify the version of the Linux distribution for which you are creating the template:

%osver

б

The specified name will be assigned to the subdirectory that will denote the version of your Linux distribution (e.g., /vz/template/centos-custom/6).

c %osarch. Provide the information about the microprocessor architecture where the OS EZ template is to be run:

%osarch

x86_64

You can set the value of the %osarch parameter to one of the following:

* x86: specify if you plan to run the template on x86 platforms.

* x86 64: specify if you plan to use the template on x86-64 platforms.

As the template being created is intended for use on x86-64-bit platforms, the %osarch parameter is set to x86 64.

d %packages. Indicate the packages to include in the template.

The names of the packages must correspond to the names of real packages (with or without package versions, for example, wget or wget=1.9.1) that are stored in the repository used for the OS template (in our case, for CentOS 5). The specified packages will be downloaded from the package repository and installed on the server when you will cache the OS template.

Note: If you are creating a template for Debian-based distributions (e.g., Debian, Ubuntu), you need to specify in this step three parameters: %packages 0, %packages 1, and %packages. This is explained by the fact that the installation of such distributions is carried out in three stages. If you do not know which packages to include, consult the documentation for the respective distribution.

%package_manager. Specify the package manager to use for handling the template. е

%package_manager rpm47x64

For the full list of package managers, see Available Package Managers below.

%repositories. Define the list of repositories storing packages for the template: f

```
%repositories
$CE_SERVER/centos/6/os/x86_64
$CE_SERVER/centos/6/updates/x86_64
```

All the listed parameters are mandatory and must be specified in any metafile. You can also set a number of supplementary parameters in your metafile (e.g., version and release). For detailed information on all available parameters, see the vzpkg.metafile manual pages. For metafile samples, go to the /usr/share/vztt/samples directory and look for the metafile file in the subdirectory corresponding to specific Linux distributions (e.g., /usr/share/vztt/samples/centos-6-x86 64/metafile).

3 Save the file.

Metafiles for Application Templates

The example above explains in detail how to create a metafile for an OS template. The process of creating a metafile for an application template is similar to that described above, except for the following:

Add the *appname* parameter to the file to specify a name for the application template, for example:

```
%appname
php-customized
```

- Do not include the %package_manager, %upgradable_versions, and %distribution parameters in the file. These parameters are allowed for OS templates only.
- Make sure that the value of the <code>%osname</code> parameter corresponds to the name of the directory of the Linux distribution under which the application template is to be run. For example, if you are creating an application template for CentOS 6 installed in the /vz/template/centos directory, set this value to centos:

%osname centos

• Ensure that the value of the <code>%osver</code> parameter corresponds to the version of the respective Linux distribution. For example, for CentOS 6 installed in the /vz/template/centos/6 directory, set this value to 6:

%osver 6

Available Package Managers

Depending on the Linux distribution for which you are creating the template, set the following values for the package_manager parameter:

x86 Linux distributions

- rpm49db5x86: Fedora 17
- rpm49x86: Fedora 15 and 16
- rpm47x86: Red Hat Enterprise Linux 6 and CentOS 6
- rpm44x86: Red Hat Enterprise Linux 5 and CentOS 5
- rpm43x86: Red Hat Enterprise Linux 3 and 4, CentOS 3 and 4
- rpmzypp44x86: SUSE Linux Enterprise Server 11 with Service Pack 2
- rpm41x86: SUSE Linux Enterprise Server 10 and SUSE Linux 10.x
- rpm41s9x86: SUSE Linux Enterprise Server 9
- rpmzypp49x86: openSUSE 12.1
- dpkg: Debian and Ubuntu

x86-64 Linux distributions

- rpm49db5x64: Fedora 17
- rpm49x64: Fedora 15 and 16
- rpm47x64: Red Hat Enterprise Linux 6 and CentOS 6
- rpm44x64: Red Hat Enterprise Linux 5 and CentOS 5
- rpm43x64: Red Hat Enterprise Linux 3 and 4, CentOS 3 and 4
- rpmzypp44x64: SUSE Linux Enterprise Server 11 with Service Pack 2

- rpm41x64: SUSE Linux Enterprise Server 10 and SUSE Linux 10.x
- rpm41s9x64: SUSE Linux Enterprise Server 9
- rpmzypp49x64: openSUSE 12.1
- dpkgx64: Debian and Ubuntu

Creating the Template with vzmktmpl

In the last step, you use the vzmktmpl utility to create the template. To make a template with this utility, you need to specify the path to

- Metafile that defines all parameters for the template; see **Creating Metafiles** (p. 17) for details on metafiles.
- Scripts that are to be executed at different stages of the template life cycle (e.g., when caching an OS template or adding an application template to a Container). Each template should have its own set of scripts optimized for use with the Linux distribution for which the template is created. To learn what scripts to specify for your template:
 - 1. Install an official template provided by Virtuozzo for the same Linux distribution for which you are creating the template. For example, if you are making a template for CentOS 6, install the CenOS 6 OS template (use the yum install command, if necessary).
 - Go to the configuration directory (/vz/template/os_name/os_version/arch/config/os/default) of the installed template.
 - 3. Look for the files starting with "pre-" and "post-" (e.g, pre-cache or post-install):

```
# ls -l /vz/template/centos/6/x86_64/config/os/default
...
-rwxr-xr-x 1 root root 453 Aug 13 22:12 post-cache
-rwxr-xr-x 1 root root 3399 Aug 13 22:12 post-install
-rwxr-xr-x 1 root root 610 Aug 13 22:12 pre-cache
-rwxr-xr-x 1 root root 943 Aug 13 22:12 pre-upgrade
...
```

For the full list of scripts, see the **vzmktmpl** section in the *Virtuozzo 6 Command Line Reference Guide*.

Once you have a metafile and the required scripts at hand, copy them to your current working directory and execute the vzmktmpl utility. For example, to create a template for CentOS 6, base it on the centos-6-custom.metafile file, and include the scripts post-cache, post-install, pre-cache, and pre-upgrade in the template, you can run this command:

vzmktmpl --pre-cache pre-cache --pre-upgrade pre-upgrade --post-cache post-cache -post-install post-install centos-6-custom.metafile

Upon the command completion, the created template is put to your current working directory:

ls
centos-custom-6-x86_64-ez-1.0-1.noarch.rpm
...

To start using the new OS template, install it on the server using the vzpkg install template command and cache it with the vzpkg create cache command.

Setting Up Repositories and Proxy Servers for EZ Templates

If you are going to use OS and application EZ templates in Containers, you first need to have one or more repositories with software packages prepared for these EZ templates. Package repositories are required for the EZ templates functioning due to the fact that these templates do not carry all the necessary package files inside themselves. They contain only information about what packages are included in the corresponding EZ template and from what repository they should be downloaded. In Virtuozzo, you can make use of the following package repositories:

- Default repositories. When you install an EZ template on the server, it is pre-configured to use official vendor's file sources (e.g., RPMs from the Fedora website) and a number of packages provided by Virtuozzo and needed for the correct EZ template functioning. So, you can start using the default repositories right after the EZ template installation on the server. Please note that the default repositories are provided for non-commercial versions of Linux distributions only.
- Local repositories. You can build your own local repositories, which allows you:
 - To greatly save on network bandwidth when deploying package updates to several servers in your network.
 - To organize your own package repository if public repositories provided by Linux OS and application vendors are not compatible with a vzpkg tool used to manage EZ templates.

Note: The vzpkg tool supports all the repositories that can be used by the yum utility (version 2.4.0 and higher) and the apt utility.

Repositories for storing software packages and updates for Red Hat Enterprise Linux distributions.

Along with setting up the aforementioned package repositories, you can also create special caching proxy servers and use them to efficiently manage your OS and application EZ templates.

Managing Default Repositories

When you install an OS EZ template on the server, it is preconfigured to use one or several package repositories storing Linux OS vendor's file sources. The path to the repositories for most OS EZ templates and their application EZ templates is automatically set during the EZ template installation in the mirrorlist or repositories files located in the

/vz/template/<os_name>/<os_version>/<arch>/config/os/default directory.
Thus, you do not have to perform any additional operations to start using an installed OS EZ
template (i.e. cache it and create Containers on its basis). The only requirement your system must
meet is to have an active Internet connection to access the servers where the preconfigured
repositories are located.

Let us assume that you want to use the 32-bit version of Fedora 16 to base your Containers on. To do this, you install the fedora-core-16-x86-tmpl-4.0.0-17.swsoft.noarch.rpm EZ template on the server:

After the OS EZ template has been successfully installed, you can explore the default repositories for Fedora 16 in the /vz/template/fedora/16/x86/config/os/default/mirrorlist file. For example:

```
# cat /vz/template/fedora/16/x86/config/os/default/mirrorlist
$SW_SERVER/download/mirrors/fedora-core-16
$SW_SERVER/download/mirrors/updates-released-fc16
http://mirrors.fedoraproject.org/mirrorlist?repo=fedora-16&arch=i386
http://mirrors.fedoraproject.org/mirrorlist?repo=updates-released-f16&arch=i386
```

This file lists the repositories set to handle the Fedora 16 OS EZ template:

- Repositories on the official Web server are defined in the first two lines. \$SW_SERVER denotes the string whose value is specified in the /vz/template/conf/vztt/url.map file. In our case, this string is the URL of the official Web server. The repositories on the official Web server keep a number of software packages needed for the correct operation of the fedora-core-16-x86 template. Along with \$SW_SERVER, the url.map file contains the list of URLs for all Linux distributions supported by Virtuozzo and having official repositories.
- Repositories on the Fedora web server are defined in the third and fourth lines. These repositories store all RPM packages for the Fedora 16 distribution.

The priority according to which software packages are downloaded from the specified servers is determined by the repositories order in the mirrorlist file. So in the example above, RPM packages from the official Web server are downloaded first and, after that, all the packages from the Fedora server.

Notes:

1. You can use the vzpkg info *OS_template_name* mirrorlist repositories command to view the mirrors and repositories for specific OS templates.

2. Commercial Linux distributions (e.g., Red Hat Enterprise Linux) do not have official repositories. You need to manually set up software repositories for such distributions before you can start using them. For more information, see to **Setting Up Repositories with vzcreaterepo** (p. 29).

Software packages are downloaded and installed on the server from package repositories when you:

- Cache an OS EZ template.
- Update an existing OS EZ template cache (provided that new packages are available in the repository).
- Add an application EZ template or package to a Container for the first time.

• Update an EZ template or software package in a Container.

You can set up your own repositories (e.g., storing unofficial software packages) for EZ templates. To do this, create the repositories file in the

/vz/template/<os_name>/<os_version>/<arch>/config/os/default directory on the server, if it is not present, and specify the path to the desired repository. For example, to add the extra repository at http://mirrors.dotsrc.org/jpackage/ and keeping Java packages for Fedora 16:

- 1 Create the /vz/template/fedora/16/x86/config/os/default/repositories file on the server.
- **2** Add the following string to the file:

http://mirrors.dotsrc.org/jpackage

3 Save the file.

Creating a Local Repository

Along with using pre-configured repositories, you can create local repositories and configure for handling packages for your EZ templates. Organizing your own local repositories results in less bandwidth consumption and rapid software updates to Containers. You may also want to build a local repository if OS vendors or third-party software developers set up repositories that are not compatible with the vzpkg tool.

Note: The vzpkg tool supports all the repositories that can be used by the yum (version 2.4.0 and higher) and apt utilities. For detailed information on these utilities, see their man pages.

The process of setting up a local repository includes the following main steps:

- **1** Obtaining software packages comprising the given Linux distribution. The easiest way of doing it is to copy the necessary packages from your distribution disks or the OS vendor's website.
- 2 Creating the metadata repository from a set of the copied software packages with the createrepo utility. This step can be omitted if you are going to create a repository which will be a mirror of a public repository.
- **3** Making your repository accessible for Containers users. You can let Container users access your repository in one of the following ways:
 - By using the http protocol. In this case the repository should represent a website containing software packages for the EZ template.
 - By using the ftp protocol. In this case the repository should represent an FTP site containing software packages for the EZ template.
 - By using the file protocol. In this case the repository should represent a directory path (e.g. on your local server) containing software packages for the EZ template.

While the first two protocols allow you to remotely (i.e. from servers located in other networks) access the created repository, the third one can be used within your local server only.

Example 1: Creating a Local Repository for Fedora 16

Let us assume that you want to build a local package repository for the Fedora 16 OS EZ template where the RPM packages for Fedora 16 will be downloaded and stored. The repository will be used by servers from both your local and other networks, and it will allow downloading packages through the http protocol. In our example, we presume the following:

• The package repository will be located inside Container 101. You can use any OS template to base the Container on.

Note: We recommend that you always place your local repositories inside separate Containers not to compromise the server security. In particular, it is of significant importance if you are going to provide access to your repositories through the http and ftp protocols.

- Container 101 is started. It has the IP address of 123.145.145.123 and can be accessed from other networks.
- The apache web server is running inside Container 101 and the default document root for apache is /var/www/html, i.e. the apache web server stores its sites in the /vz/root/101/var/www/html directory on the server.
- The apache user and group inside Container 101 are apache.

To create a local repository for Fedora 16, do the following:

1 Install the fedora-core-16-x86 OS EZ template (if it is not already installed):

2 Change to the /vz/root/101/var/www/html directory, and create two subdirectories within it:

Note: You can also log in to Container 101 and perform the operations described in **Steps 2-8** from inside the Container. In this case your working directory inside Container 101 must be /var/www/html, and you will need to install the createrepo package inside the Container and grant the Container access to the CD-ROM drive on the server.

• The subdirectory where the base RPM packages for Fedora 16 will be stored:

mkdir -p download/fedora-core/16/i386/os/Fedora/RPMS

- The subdirectory where the updated versions of RPM packages for Fedora 16 will be stored:
- # mkdir -p download/fedora-core/updates/16/i386
- **3** Copy all the packages comprising the Fedora 16 distribution (e.g., from your Fedora distribution disks) to the download/fedora/16/i386/os/Fedora/RPMS directory on the server.
- 4 Get the updates for Fedora 16, and put them to the download/fedoracore/updates/16/i386 directory on the server.
- 5 Install the createrepo package on the server, for example:

```
1:createrepo
```

- 6 Change to the /vz/root/101/var/www/html directory and create the following metadata repositories:
 - For the Fedora 16 base RPM packages:
- # createrepo download/fedora/16/i386/os
 - For the updated versions of the Fedora 16 RPM packages:

```
# createrepo download/fedora-core/updates/16/i386
```

Creating the package metadata repository may take some time depending on the speed of your processor and hard disk drive.

7 Create a directory for storing mirror site lists. In our case, the lists will be kept in the /vz/root/101/var/www/html/download/mirrors directory:

```
# mkdir -p download/mirrors
```

- 8 Create the mirror list files and set the path to your local repository. For example, you can do this as follows:
 - For the Fedora 16 base RPM packages:

echo 'http://123.145.145.123/download/fedora/16/i386/os/' >> download/mirrors/fedoracore-16

• For the updated versions of the Fedora 16 RPM packages:

```
# echo 'http://123.145.145.123/download/fedora/updates/16/i386' >>
download/mirrors/updates-released-fc16
```

The aforementioned commands create the fedora-core-16 and updates-released-fc16 files in the /vz/root/101/var/www/html/download/mirrors directory on the server and add the

http://123.145.145.123/download/fedora/16/i386/os/Fedora/RPMS and http://123.145.145.123/download/fedora/updates/16/i386 strings to them, respectively.

9 Open the /vz/template/conf/vztt/url.map file on the server for editing (e.g., by using vi), and change the value of the \$FC_SERVER variable as follows:

\$FC_SERVER http://123.145.145.123

10 Grant the apache user and the apache group access to the created repositories inside Container 101 by executing the following command on the server:

prlctl exec 101 chown -R apache.apache /var/www/html/download

Example 2: Accessing the Repository via the file protocol

Once you set up a local repository by following the instructions in the example above, you can start using the vzpkg tool to obtain RPM packages for the Fedora 16 EZ template from this repository. You can connect to these repositories via the http protocol from both remote and local servers.

You can further speed up the process of distributing RPM packages across your repository for those Containers that reside on your local server (that is, on the server where the repositories are stored). To do this, configure your system to use the file protocol instead of http to connect to your repositories:

1 Open the /vz/template/fedora/16/x86/config/os/default/mirrorlist file on the server and comment the strings containing \$FC_SERVER:

#\$FC_SERVER/download/mirrors/fedora-core-16

#\$FC_SERVER/download/mirrors/updates-released-fc16

- 2 Execute the following commands to create the repository files:
 - To create the

/vz/template/fedora/16/x86/config/os/default/repositories file on the server and to make it point to the Fedora 16 base RPM packages from your local repository:

echo 'file:///vz/root/101/var/www/html/download/fedora/16/i386/os/Fedora/RPMS' >>
/vz/template/fedora/16/x86/config/os/default/repositories

To create the

/vz/template/fedora/16/x86/config/os/default/repositories file on the server and to make it point to the updated versions of the Fedora 16 RPM packages from your local repository:

echo 'file:///vz/root/101/var/www/html/download/fedora/updates/16/i386' >>
/vz/template/fedora/16/x86/config/os/default/repositories

Setting Up a Proxy Server for EZ Templates

You can set up special caching proxy servers and use them to efficiently manage your OS and application EZ templates. The following figure illustrates an example network configuration that contains two servers and a separate proxy server:

In this configuration:

- The caching proxy server sits between the servers (*Hardware Node 1* and *Hardware Node 2*) and keeps a number of EZ templates and the repositories (*Repository 1*, *Repository 2*, and *Repository 3*) storing the packages for these EZ templates.
- When either server requests certain packages from any repository for the first time, these packages are first downloaded to the proxy server where they are cached and then downloaded to the corresponding server.

- When a server requests a package that is already available in the cache on the proxy server and none of the repositories has updates for the package, this package is immediately downloaded to the server from the proxy server. If any updates are available in the official repositories, the procedure of handling these updates is identical to that of the main packages: The update is downloaded to the proxy server where it is cached and then retransmitted to the corresponding server.
- A special script is automatically run on the proxy server at set intervals. During its execution, the script creates a local repository from the cached packages. All you have to do is to configure the vzpkg tool to use packages from this repository instead of obtaining them from remote repositories.

Setting up a proxy server for managing EZ templates has the following advantages:

- 1 Your Internet bandwidth consumption is greatly reduced because all packages are downloaded to the proxy server only once and can then be used by any server on your network.
- 2 You can more rapidly apply software updates to Containers since the proxy server where the downloaded packages are stored resides in the local network.
- 3 You can always have the software packages included in OS EZ templates at hand and do not have to worry whether they have been changed in or removed from their original repositories. The Virtuozzo script running on the proxy sever does not remove any cached packages; so it is up to you when to delete a specific package, if at all.

Setting Up a Proxy Server

To make a server act as a caching proxy server for EZ templates, you need to install the vzpkgproxy package on this server. vzpkgproxy is located in the /virtuozzo/RPMS directory of your Virtuozzo distribution and can be installed with the rpm -i command on servers (including Containers) meeting the following requirements:

- The Apache httpd server, version 2.0.53 and higher, is installed on the server.
- The createrepo package, version 0.4.2 and higher, is installed on the server.

Keep in mind that you may also need to install a number of additional packages to satisfy the vzpkgproxy dependencies.

By default, the caching proxy server does not allow connections from external hosts. To allow external connections, you need to edit the /etc/httpd/conf.d/vzproxy.conf file as described below:

1 Locate the following section in the vzproxy.conf file.

```
<Proxy *>
Order deny,allow
Deny from all
# Enter all clients here
Allow from localhost.localdomain
</Proxy>
```

2 Replace localhost.localdomain with the hostnames of external servers you want to be able to connect to the proxy server. For example, to allow connections from the myserver1.com and myserver2.com servers, you can edit the section as follows:

```
<Proxy *>
Order deny,allow
Deny from all
# Enter all clients here
Allow from myserver1.com myserver2.com
```

</Proxy>

You can also remove the string Deny from all and change the string Allow from localhost.localdomain to Allow from all to allow all external hosts to connect to the proxy server.

Once you edit the /etc/httpd/conf.d/vzproxy.conf file, you need to tell the vzpkg tool to use the packages from the local repository on the proxy server while handling EZ templates. To do this, edit the /etc/vztt/vztt.conf file on the server and specify the following parameters:

- The URL of the proxy server, the port number where the httpd daemon is listening, and the path to the directory where the EZ templates local repository is located as the value of the VZTT_PROXY parameter. For example, if your proxy server has the 127.123.123.127 IP address assigned, the httpd daemon running on the proxy server is listening on port 8080, and the local repository is stored in /var/www/html/download, you should set the VZTT_PROXY parameter to http://127.123.123.127:8080/download.
- The URL of the proxy server and the port number where the httpd daemon is listening as the value of the HTTP_PROXY parameter. For example, you should set this value for the aforementioned proxy server to http://127.123.123.127:8080. Keep in mind that you also need to set the HTTP_PROXY_PASSWORD and HTTP_PROXY_USER parameters in the /etc/vztt/vztt.conf file if the access to your proxy server is password-protected.

Configuring Proxy Server Parameters

You can configure a number of proxy server parameters to meet your demands:

- Configure the CACHE_DISABLE parameter in the /etc/vzpkgpoxy/vzpkgproxy.conf file on the proxy server to specify the hosts to be excluded from the caching process. By default, the proxy server caches the packages from all external hosts that are allowed to connect to the proxy server.
- Configure the port number on which the httpd daemon running on the proxy server is listening. To do this, specify the desired port number in the /etc/httpd/conf.d/vzproxy.conf file on the proxy server. The default port number is 8080.
- Configure the REPO_DIR parameter in the vzpkgproxy.conf file to change the path to the directory where the local repository created on the basis of the cached packages will be stored. By default, this directory is /var/www/html/download.

Setting Up Repositories with vzcreaterepo

Virtuozzo 6 provides you with a special utility, vzcreaterepo, to facilitate the process of setting up repositories for RHEL-like distributions, including repositories for Red Hat Enterprise Linux 5.

Note: The current version of vzcreaterepo does not support creating repositories for Red Hat Enterprise Linux 6 and all versions of openSUSE and SUSE Linux Enterprise Server.

The process of setting up a repository with vzcreaterepo includes the following steps:

- 1 Installing an OS template for which you plan to set up the repository.
- 2 Obtaining the Linux distribution files to use as the basis for creating the repository.

Note: Always try to get the most recent versions of Linux distributions. For example, when creating a repository for Red Hat Enterprise Linux 5 and choosing between two versions 5.7 or 5.8, go with version 5.8. This will help you avoid possible problems with vzcreaterepo that is optimized for work with the latest versions of Linux distributions.

- **3** Creating the repository with the vzcreaterepo utility from the prepared distribution files.
- 4 Configuring the vzpkg template management tool to contact the created repository. As a rule, vzcreaterepo automatically configures the vzpkg tool to work with newly created repositories. If some extra configuration is required, the utility will inform you of the steps to complete.

The example below assumes the following:

- You want to create a repository for the x64 version of Red Hat Enterprise Linux 5.8.
- The redhat-e15-x86_64 OS template is installed on your server.
- The full path to the RHEL 5.8 ISO image on the server is /mnt/iso/rhel-server-5.8x86_64-dvd.iso.

To set up a repository, you can run this command:

```
# vzcreaterepo -t redhat-el5-x86_64 -i /home/rhel-server-5.8-x86_64-dvd.iso
```

By default, vzcreaterepo sets up the repository in the /vz/template/repos/download/redhat/el5/x86_64 directory. If necessary, you can specify another location for your repository using the -d option.

To configure your repository to also store package updates for RHEL 5.8, you need to specify a number of additional options when executing the vzcreaterepo command, for example:

```
# vzcreaterepo -t redhat-el5-x86_64 -i /home/rhel-server-5.8-x86_64-dvd.iso --ctid 101
--ip 192.168.98.198 --hostname myrhelupdates.com --nameserver 192.168.0.1 -e
user@mycompany.com
```

Along with setting up a repository for RHEL 5.8 in the $/vz/template/repos/download/redhat/el5/x86_64$ directory, this command:

- Creates Container 101 with the IP address of 192.168.98.198 and the hostname of myrhelupdates.com.
- Configures for the Container the nameserver with the IP address of 192.168.0.1.
- Asks you for the user name and password to log in to the Red Hat Network (RHN). Use the credentials you provided when registering in RHN.
- Registers the Container in the Red Hat Network with the email address user@mycompany.com. Replace user@mycompany.com with the email address you specified when setting up your account in the Red Hat Network.
- Downloads updated packages from the RHEL web site to the Container and creates an update repository from these packages.

Notes:

1. An active Internet connection is required to connect to the Red Hat website and register in the Red Hat Network.

2. You must have an active RHN account before running the vzcreaterepo command to create a repository with package updates. The account must allow you to download updates for the system for which you are setting up the repository.

Preparing an OS EZ Template for Container Creation

Although you can create Containers without having to prepare OS EZ templates first, doing so provides more control over the entire process and helps avoid problems which might be caused by a slow Internet connection, for example. OS EZ template preparation includes:

- **1** Installing an OS EZ template on the server.
- 2 Creating an OS EZ template cache, with or without preinstalled applications.

For details on how to start creating Containers once caching has been done, see the *Virtuozzo 6* User's Guide.

Installing OS EZ Templates

To install a new OS EZ template on the server, use the vzpkg install template command. For example, to install the CentOS 6 EZ (x86) template, you can do this:

You may also want to check that the template has been installed successfully:

```
# vzpkg list
centos-6-x86
```

The centos-6-x86 EZ template has been installed on the server in the /vz/template/centos/6 directory.

Note: Before caching OS EZ templates, you may need to set up a local package repository (e.g., for commercial distributions like Red Hat Enterprise Linux). For details on how to manage package repositories, see **Setting Up Repositories and Proxy Servers for EZ Templates** (p. 21).

Creating Clean OS EZ Template Caches

You can use a clean OS EZ template cache to create an empty Container without any custom applications installed. To create a clean OS EZ template cache, use the vzpkg create cache command, specifying an OS EZ template to cache:

vzpkg create cache centos-6-x86

The created archive is put to the /vz/template/cache directory on the server:

```
# ls /vz/template/cache
centos-6-x86.plain.ploop.tar.lzrw
```

Creating OS EZ Template Caches with Preinstalled Application Templates

You can use an OS EZ template cache with preinstalled application templates to quickly create multiple identical Containers without having to install applications manually or wait until they are installed automatically to each Container after its creation. The best way to create such a cache is:

1 Make a custom sample configuration file with information on the OS EZ template to cache and application EZ templates to preinstall. For example:

cp /etc/vz/conf/ve-basic.conf-sample /etc/vz/conf/ve-centos-6-x86-mysql-devel.confsample

Note: If you already have a custom sample configuration file created in Parallels Server Bare Metal 5 or earlier and having application EZ templates specified in it, you can reuse it instead of creating a new one.

2 Add the OS EZ template and application EZ template information to the new configuration file. Each OS and application template name must be preceded by a dot. Multiple consecutive application EZ template names must be separated by white spaces. For example:

```
# cd /etc/vz/conf
# echo 'OSTEMPLATE=".centos-6-x86"' >> ve-centos-6-x86-mysql-devel.conf-sample
# echo 'TEMPLATES=".mysql .devel"' >> ve-centos-6-x86-mysql-devel.conf-sample
```

3 Run the vzpkg create appcache command with your configuration file as an option. For example:

vzpkg create appcache --config centos-6-x86-mysql-devel

Note: If the resulting cache already exists, it will not be recreated and you will see a corresponding message.

The resulting archive can be found in the /vz/template/cache directory on the Hardware Node. You can check that it exists and includes necessary application templates with the following command:

```
# vzpkg list appcache
centos-6-x86
    mysql
    devel
```

2012-07-20 16:51:36

Installing Application EZ Templates on the Server

The same way as you use an OS EZ template in a Virtuozzo system to create any number of Containers on its basis and share its resources, you can use application EZ templates to share application files among any number of Containers.

To install a new application EZ template on the server, you can use the vzpkg install template command. For example, to install the mysql EZ template intended for use on the CentOS 5 distribution, you can execute the following command:

The mysql EZ template is installed into the

/vz/template/centos/6/x86/config/app/mysql directory on the server. To check that the installation was successful, you can use the vzpkg list command:

```
# vzpkg list
centos-6-x86 2012-07-21 02:22:45
centos-6-x86 mysql
```

As you see, the mysql EZ template is now available on the server and can be added to Containers.

Viewing Installed EZ Templates on the Server

The vzpkg list command allows you to list the EZ templates installed on the server. They may be already used or not used by certain Containers:

```
# vzpkg list -0
centos-6-x86
centos-6-x86_64
```

2012-07-10 13:16:43

Using the -0 option with the vzpkg list command, you can list only the OS EZ templates installed on the server. The time next to an OS EZ template indicates when the template was cached.

Specifying a Container ID as the parameter, vzpkg list prints the EZ templates used by the specified Container:

vzpkg list 101
centos-6-x86_64

2012-07-10 13:16:43

Viewing Available EZ Templates on the Server

The vzpkg list --available command allows you to list the EZ templates that are available in the official remote repositories but not installed on the server yet. For example, to list all EZ templates available for installation on your server, you can run this command:

vzpkg list --available

The vzpkg list command also supports using wildcards. So you can execute the following command to view all MySQL application templates intended for use with different versions of CentOS:

```
# vzpkg list --available mysql-centos*
mysql-centos-4-x86 pvc-templates-32
mysql-centos-5-x86 pvc-templates
mysql-centos-5-x86_64 pvc-templates
mysql-centos-6-x86 pvc-templates-32
mysql-centos-6-x86_64 pvc-templates-32
```

Keeping EZ Templates Up To Date

Virtuozzo allows you to update OS and application EZ templates as follows:

- Update any of the EZ templates installed on the server.
- Update the caches of OS EZ templates installed on the server.
- Update the packages that are included in the EZ templates (OS and application) applied to specific Containers.

All the aforementioned operations are described in the following subsections in detail.

Updating EZ Templates on the Server

Sometimes, you may need to update one or more EZ templates (either OS or application) installed on your server. The process of updating an EZ template includes updating its configuration files in the /vz/template/<os_name>/<os_version>/<arch>/config directory on the server.

The recommended way of updating an installed EZ template is to use the vzpkg update template command. When executed, this command tells the vzpkg utility to access the official remote repositories and check for available OS and application EZ templates updates. For example, you can run the following command to update the CentOS 5 OS EZ template installed on the server:

vzpkg update template centos-6-x86

You can update a number of EZ templates at once by specifying the corresponding packages and separating them by spaces. For example, the following command

vzpkg update template centos-6-x86 redhat-el6-x86

simultaneously updates the CentOS 6 and Red Hat Enterprise Linux 6 OS EZ templates installed on the server.

Updating OS EZ Template Caches

Virtuozzo has two types of OS EZ template caches: with and without preinstalled application templates. Each cache type can be updated with a corresponding command.

Note: To update the cache of a commercial OS EZ template (e.g., Red Hat Enterprise Server 5 or SLES 10), you should first update software packages in the remote repository used to handle this OS EZ template and then update the cache. For more information on how to manage repositories for commercial Linux distributions, see **Setting Up Repositories and Proxy Servers for EZ Templates** (p. 21).

Updating OS EZ Template Caches without Preinstalled Applications

If you need to update an OS EZ template cache without preinstalled application templates, use the vzpkg update cache command.

When executed, vzpkg update cache checks the template cache directory on the server (the default is /vz/template/cache) and updates all existing tarballs there. To update a particular cache, specify the corresponding OS EZ template name. For example, to update the cache of the centos-6-x86 OS EZ template, run the following command:

```
# vzpkg update cache centos-6-x86
```

When executed, vzpkg update cache also appends the -old suffix to old tarball names (e.g., centos-6-x86.plain.ploop.tar.lzrw-old):

```
# ls /vz/template/cache
```

centos-6-x86.plain.ploop.tar.lzrw centos-6-x86.plain.ploop.tar.lzrw-old

You can also pass the -f option to vzpkg update cache to remove the existing cache and create a new one instead.

If the vzpkg update cache command cannot find caches for one or more OS EZ templates installed on the server, it creates those in the /vz/template/cache directory.

Updating OS EZ Template Caches with Preinstalled Applications

If you need to update an OS EZ template cache with preinstalled application templates, use the vzpkg update appcache command with the --update-cache option. For example, to update a centos-6-x86 OS EZ template cache with preinstalled mysql, devel, and php, run the following:

vzpkg update appcache --ostemplate centos-6-x86 --apptemplate mysql,php,devel -update-cache

Updating EZ Templates Packages Inside a Container

Virtuozzo allows you to update software packages of the OS EZ template a Container is based on and of any application EZ templates applied to the Container. You can do it by using the vzpkg update utility. Assuming that Container 101 is based on the redhat-e15-x86 OS EZ template, you can issue the following command to update all packages included in this template:

```
# vzpkg update 101 redhat-el5-x86
 Updating: httpd
                                ################################## [1/4]
 Updating: vzdev
                                ################################### [2/4]
 Cleanup : vzdev
                                ################################# [3/4]
 Cleanup : httpd
                                Updated: httpd.i386 0:2.0.54-10.2 vzdev.noarch 0:1.0-4.swsoft
Complete!
Updated:
                                 0:2.0.54-10.2
httpd
                       i386
vzdev
                       noarch 0:1.0-4.swsoft
```

Notes:

1. A Container has to be running in order to update EZ templates inside this Container.

2. If you are going to update the cache of a commercial OS EZ template (e.g. Red Hat Enterprise Server 5 or SLES 10), you should first update software packages in the remote repository used to handle this OS EZ template and then proceed with updating the EZ template cache. Detailed information on how to manage repositories for commercial Linux distributions is provided in the **Setting Up Repositories and Proxy Servers for EZ Templates** section (p. 21).

As you can see from the example above, the httpd and vzdev applications have been updated for the redhat-el5-x86 OS EZ template. If you wish to update all EZ templates (including the OS EZ template) inside Container 101 at once, you should execute the following command:

In the example above, only the hwdata package inside Container 101 was out of date and updated to the latest version.

Adding Application EZ Templates to Containers

To add an application EZ template to an existing Container, you should use the vzpkg install command. To successfully add an application EZ template to a Container, this Container must be running. Otherwise, it is impossible to run the installation process in the Container context.

In the example below, the mysql application EZ template meant for the usage with Red Hat Enterprise Linux 5 and already installed on the host is added to Container 101:

Copying EZ Templates to Another Server

Virtuozzo allows you to copy the installed OS and application EZ templates from one server to another using the vzmtemplate utility. For example, you can copy the centos-6-x86 OS template installed on the source server to the destination server with the IP address of 192.168.0.9 by executing the following command:

vzmtemplate -z root@192.168.0.9 centos-6-x86

During the command execution, vzmtemplate will do the following:

- 1 Ask you for the password of the root user on the destination server.
- 2 Check whether the centos-6-x86 OS EZ template already exists on the destination server. If this templates is installed on the Destination Node, the command will exit.
- 3 Copy the centos-6-x86 configuration files from the source server to the destination server. Please keep in mind that the centos-6-x86 OS EZ template is not removed from the source server.
- **4** Run the vzpkg create cache command on the destination server to cache the OS EZ template and prepare it for the Container creation. Detailed information on this command is provided in the **Preparing an OS EZ Template for Container Creation** section (p. 30).

Note: If you are going to copy an application EZ template, make sure that the corresponding OS EZ template (i.e. the OS template with which the application EZ template can be used) is installed on the destination server. Otherwise, the operation will fail.

To check that the centos-6-x86 OS template has been successfully copied to the destination server, you can run the following command on this server:

vzpkg list centos-6-x86

20012-6-12 07:05:39

Removing an Application from Containers

The vzpkg remove command allows you to remove one or several application EZ templates from a Container. A session below shows you an example how to remove the mysql EZ template from Container 101:

```
# vzpkg list 101
                               2012-05-21 02:21:56
redhat-el6-x86
redhat-el6-x86 mysql
                               2012-05-21 05:36:42
# vzpkg remove 101 mysql -w
vzpkg remove 101 mysql
Removed:
mysql
mysql-server
mysql-devel
mysql-bench
perl-DBD-MySQL
# vzpkg list 101
redhat-el6-x86
                                2012-05-21 02:21:56
```

You can see that the mysql EZ template has been successfully removed from Container 101. The -w option tells the vzpkg remove command to also delete from the Container all packages having interdependencies with mysql.

Removing EZ Templates From the Server

The vzpkg remove template command allows you to remove from the host those EZ OS and application templates that you do need any more. The process of removing an EZ template includes deleting all the RPM packages comprising this template and all the caches available for this template (for EZ OS templates only). Please keep in mind that the template to be removed should not be applied to any Container. Otherwise, the template deletion will fail. A session below demonstrates how to remove the redhat-el5-x86 EZ OS template from the host:

```
# vzpkg list
redhat-el6-x86 2012-06-16 12:50:17
centos-6-x86 2012-06-18 14:23:12
# vzpkg remove template redhat-el6-x86
redhat-el6-x86 template was removed
# vzpkg list
centos-6-x86 2012-06-18 14:23:12
```

To remove an EZ application template from the server, you should additionally specify the -F option after the vzpkg remove template command. This option denotes the EZ OS template with which the EZ application template is compatible. For example, the following command can be used to remove the mailman EZ application template that is intended for running under RHEL 6 from your server:

vzpkg remove template -F redhat-el6-x86 mailman
redhat-el6-x86 mailman template was removed

You can also remove several EZ templates at once by specifying their names after vzpkg remove template and separating them by spaces. However, when handling application templates, keep in mind that you can delete only those application templates that relate to one and the same EZ OS template. For example:

vzpkg remove template -F redhat-el6-x86 sitebuilder4 mailman redhat-el6-x86 sitebuilder4 template was removed redhat-el6-x86 mailman template was removed

In this example the sitebuilder4 and mailman EZ application templates intended to run under RHEL 6 have been successfully removed from the host.

CHAPTER 4

Glossary

This glossary defines terms and spells out abbreviations used in Virtuozzo documentation. References to terms defined elsewhere in the glossary appear in italics.

Application template. A template used to install a set of applications in *Containers*. See also *Template*.

Container (or regular Container). A virtual private server, which is functionally identical to an isolated standalone server, with its own IP addresses, processes, files, users database, configuration files, applications, system libraries, and so on. Containers share one host and one OS kernel. However, they are isolated from each other. A Container is a kind of 'sandbox' for processes and users.

Guest operating system (Guest OS). An operating system installed inside a virtual machine and Container. It can be any of the supported Windows or Linux operating systems.

Hardware virtualization. A technology allowing you to virtualize physical servers at the hardware level. Hardware virtualization provides the necessary environment for creating and managing Virtuozzo virtual machines.

Operating system virtualization (OS virtualization). A technology allowing you to virtualize physical servers at the operating system (kernel) level. OS virtualization provides the necessary environment for creating and managing Virtuozzo Containers.

OS template (Operating System template). A template used to create new *Containers* with a pre-installed operating system. See also *Template*.

Package set. See Template.

Host (physical server or server). A server where the Virtuozzo software is installed for hosting Virtuozzo virtual machines and Containers. Sometimes, it is marked as Container 0.

Virtuozzo license key. A license key that you should install on the physical server to use Virtuozzo. Every physical server must have its own key installed.

Virtuozzo Storage license key. A license key for Virtuozzo Storage to use its functionality.

Memory and IOPS deduplication. A feature introduced in Virtuozzo 6.0. By caching identical files in multiple Containers it helps save memory and IOPS on the Hardware Node.

Parallels Virtuozzo Containers for Linux. An operating system virtualization solution allowing you to create multiple isolated Containers on a single physical server to share hardware, licenses, and management effort with maximum efficiency.

Private area. A part of the file system storing *Container* files that are not shared with other *Containers*.

Template (package set). A set of original application files (packages) repackaged for mounting. There are two types of templates. OS Templates are used to create new *Containers* with a preinstalled operating system. Application templates are used to install an application or a set of applications in *Containers*.

UBC. An abbreviation of User Beancounter.

User Beancounter. The subsystem of the Virtuozzo software for managing *Container* memory and some system-related resources.

Virtual Environment (VE). An obsolete designation of a Container.

Virtuozzo File System (VZFS). A virtual file system for legacy Containers.

Virtual machine (VM). A computer emulated by Virtuozzo. Like a Container, a virtual machine is functionally identical to an isolated standalone computer, with its own IP addresses, processes, files, users database, configuration files, applications, system libraries, and so on. However, unlike Containers, virtual machines run their own operating systems rather than sharing one operating system kernel.
